AI AND ANALYTICS USING ZIA

Student Admission Analytics System

1. AIM

To explore how Zia, the AI assistant in Zoho Creator, can support analytics and decision-making in a Student Admission Analytics System by presenting application summaries, identifying priority levels, organizing records, and visualizing admission and resource-planning information.

2. OVERVIEW

Zia is an AI-powered assistant available in Zoho applications. In an admission management workflow, AI and analytics can help staff understand application data, review processing and document-verification statuses, and interpret trends without manually inspecting every record. Dashboards and reports turn stored records into visual summaries that support planning and follow-up.

The Student Admission Analytics System shown in this report contains a dashboard, application entry and listing pages, an application-status board, a resource forecast report, and enrollment-trend records. These screens demonstrate the data and visual summaries that can be used alongside Zia-enabled analysis. The screenshots are placed within the procedure rather than on separate pages.

3. PROCEDURE

Step 1: Open the analytics dashboard

Open the Student Admission Analytics System and review the dashboard. Check the summary cards for total budgets, tuition fees, applications, and admissions. Review the priority-level summary and charts to identify areas that may need attention.

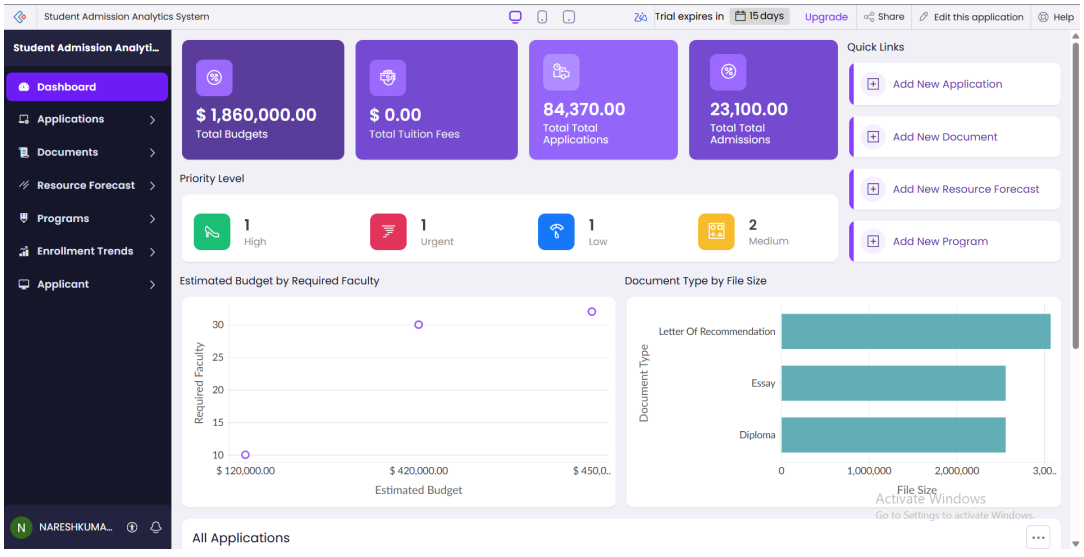

Figure 1. Dashboard with summary cards, priority levels, and analytics charts.

Step 2: Enter a student application

Navigate to Applications and open the Application form. Enter the applicant, program, application number, submission date, AI processing status, eligibility score, document verification status, notes, and priority level. Select Submit to save the record, or Reset to clear the form.

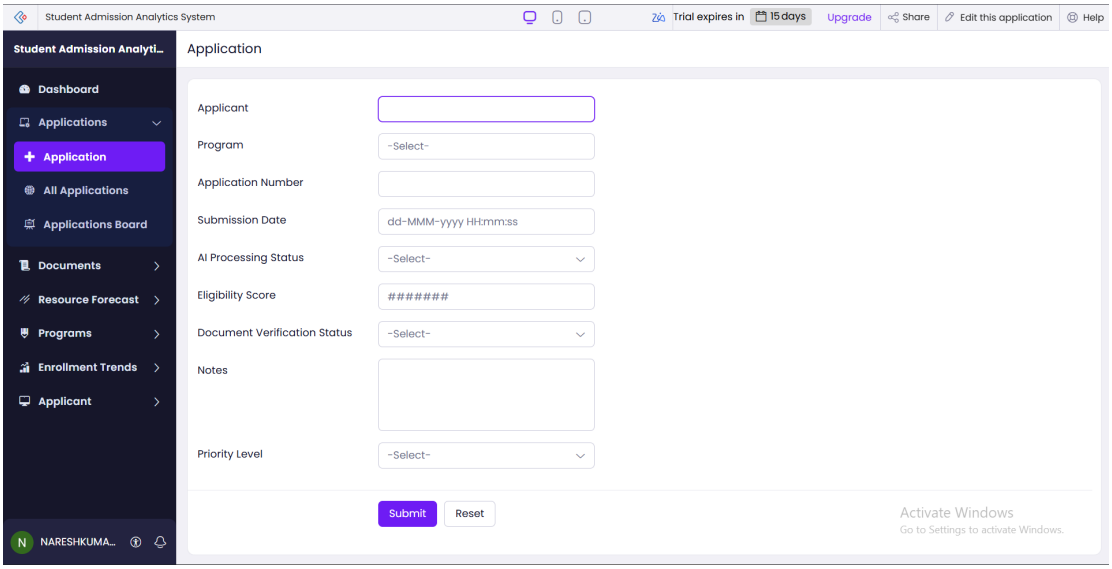

Figure 2. Application form and the fields used to capture admission information.

3. PROCEDURE (CONTINUED)

Step 3: Review all application records

Open All Applications to review the list of submitted records. Compare application numbers, submission dates, processing status, eligibility scores, and document-verification status. Use this view to identify records requiring manual review or follow-up.

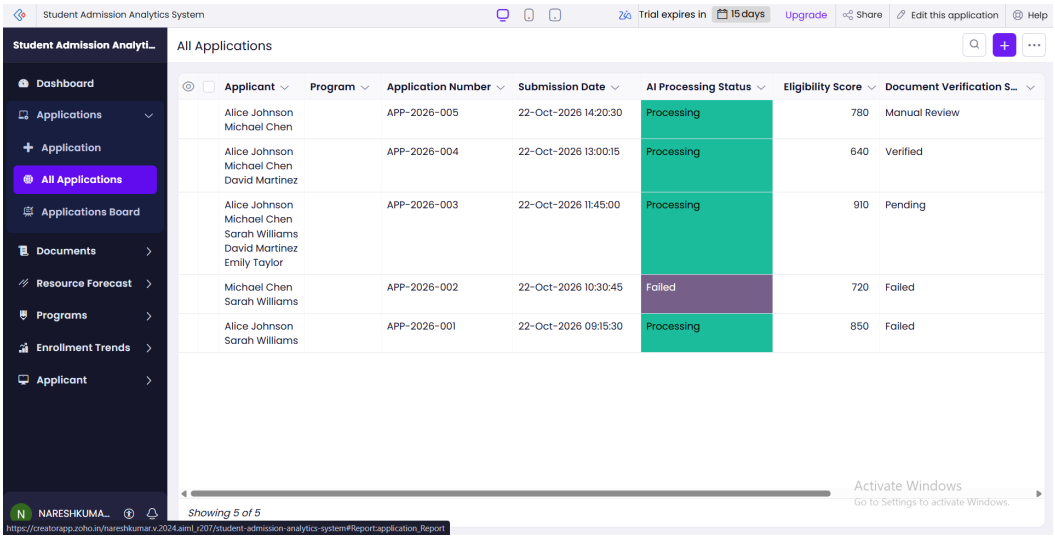

Figure 3. Application list showing processing and verification information.

Step 4: Track applications by status

Open Applications Board to view records grouped into status columns such as Failed, Completed, Pending, and Processing. This board provides a quick visual way to identify where applications are concentrated and which records may require action.

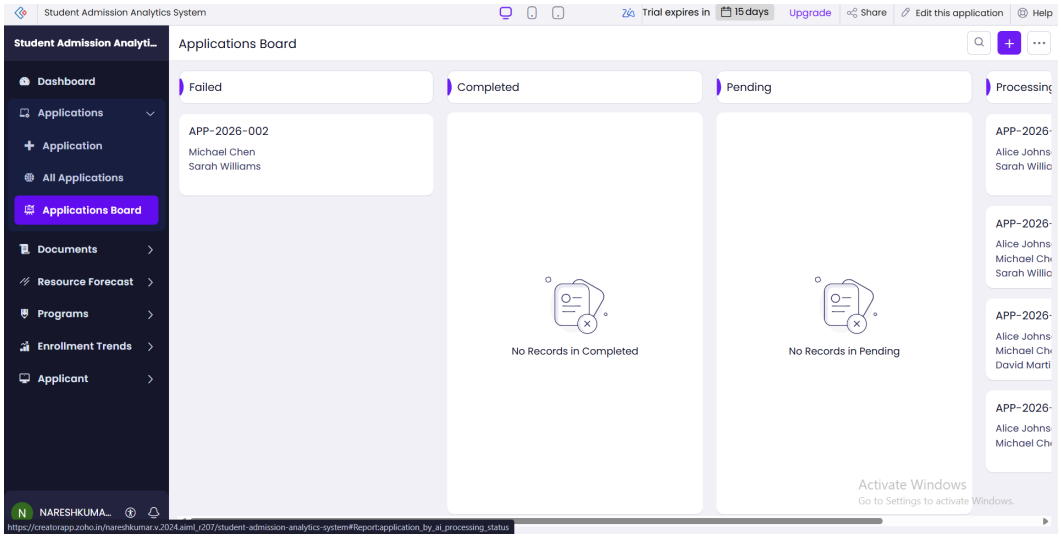

Figure 4. Application board grouped by processing status.

3. PROCEDURE (CONTINUED)

Step 5: Analyze resource forecasts

Open Resource Forecast Report. Review projected students, required classrooms, required faculty, estimated budget, and confidence level for each forecast period. These figures can help administrators plan staffing, classroom capacity, and budget allocation.

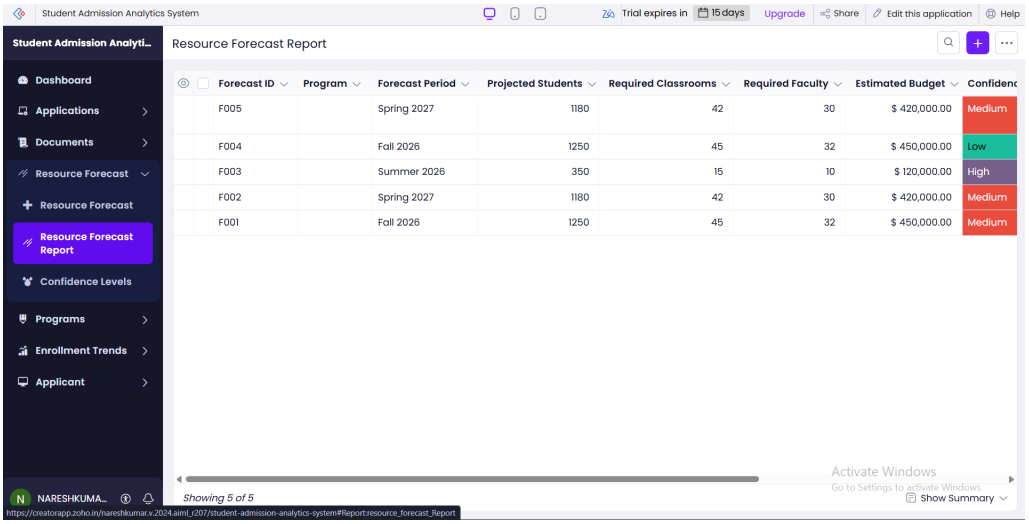

Figure 5. Resource forecast table with budget and confidence information.

Step 6: Examine enrollment trends

Open Enrollment Trends and inspect the records for each month or period. Compare total applications, total admissions, rejection rate, and average score. Use the observed trends to support admission planning and to decide where additional review or outreach may be useful.

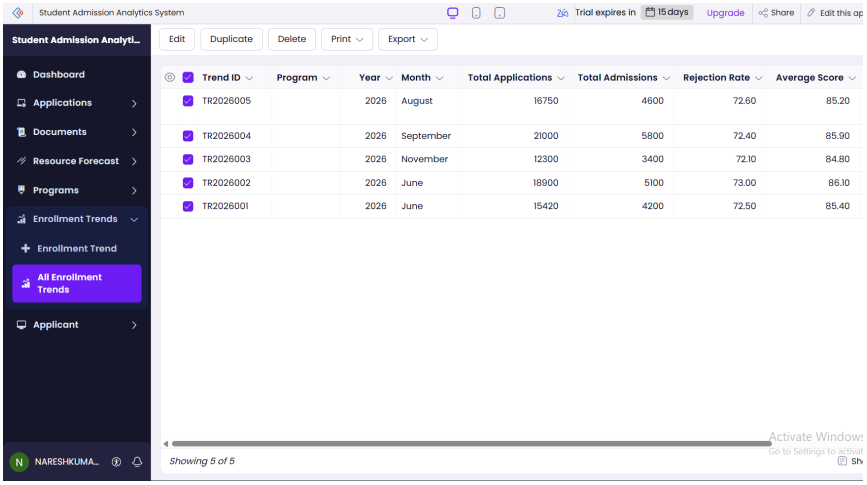

Figure 6. Enrollment-trend records for comparing application and admission metrics.

4. RESULT

The Student Admission Analytics System was reviewed successfully through its dashboard, application form, application listing, status board, resource forecast, and enrollment-trend screens. The exercise demonstrated how structured records and visual analytics can help users monitor admission activity, identify processing bottlenecks, and plan institutional resources. Zia can support natural-language exploration and AI-assisted insights where the relevant Zia features are enabled and configured in the Zoho environment.

Note: The screenshots document the application's interface and reports. They do not, by themselves, prove that a specific Zia-generated prediction or recommendation was executed. Actual AI outputs depend on the app configuration, data, and available Zoho subscription.
